# Study of $H \rightarrow \mu^{+} \mu^{-}$at $\sqrt{s}=1 \mathrm{TeV}$ at the ILC 

Constantino Calancha<br>High Energy Accelerator Research Organization (KEK), Tsukuba, Japan<br>calancha@post.kek.jp

April 19, 2013

#### Abstract

The statistical uncertainty of $\sigma\left(\nu_{e} \overline{\nu_{e}} \mathrm{H}\right) \cdot \operatorname{Br}\left(\mathrm{H} \rightarrow \mu^{+} \mu^{-}\right)$for a $125 \mathrm{GeV} / \mathrm{c}^{2}$ Standard Model Higgs boson is evaluated, in the context of the 1 TeV ILC [1] $e^{+} e^{-}$linear collider with beam state polarisation $\left(P_{e^{-}}, P_{e^{+}}\right)=(-0.8,+0.2)$, and a total integrated luminosity of $500 \mathrm{fb}^{-1}$. The study is performed in the ILD [2] detector concept using full simulation. All relevant Standard Model backgrounds are taken into account. The effect of the underlying $\gamma \gamma \rightarrow$ hadrons is taken into account by overlaying realistic amounts of $\gamma \gamma \rightarrow$ hadrons onto both signal and background events. The cross section times the branching ratio can be measured with a statistical accuracy of $44 \pm 3$ \%.

## 1 Introduction

Figure 1: Higgs couplings to SM particles as a function of their masses (left) Higgs branching ratios as a function of the Higgs mass (right).

The SM predicts a linear relation between Higgs couplings to SM particles and their masses (Fig. 1). A deviation from this prediction would be a strong indication of new physics. The precise measurement of those couplings is one of the main goals of the ILC physics program.

The recent discovery at ILC of a higgs-like boson with a mass $\sim 125 \mathrm{GeV} / \mathrm{c}^{2}$ makes possible to study many branching ratios of the decay of this boson at the ILC (Fig. 1).

In this note we study $\nu_{e} \overline{\nu_{e}} \mathrm{H}, \mathrm{H} \rightarrow \mu^{+} \mu^{-}$at 1 TeV and beam state polarisation $\left(P_{e^{-}}, P_{e^{+}}\right)=(-$ $0.8,+0.2)$, and we determine the expected statistical uncertainty for $\sigma\left(\nu_{e} \overline{\nu_{e}} \mathrm{H}\right) \cdot B r\left(\mathrm{H} \rightarrow \mu^{+} \mu^{-}\right)$.

The measurement $\nu_{e} \overline{\nu_{e}} \mathrm{H}, \mathrm{H} \rightarrow \mu^{+} \mu^{-}$is quite challenging due to the very low branching ratio $\mathrm{Br}(\mathrm{H} \rightarrow$ $\mu^{+} \mu^{-}$), only $0.02 \%$ for a Higgs boson mass of $125 \mathrm{GeV} / \mathrm{c}^{2}$. After recording $500 \mathrm{fb}^{-1}$ of data with beam polarization state $\left(P_{e^{-}}, P_{e^{+}}\right)=(-0.8,+0.2)$ we expect only $45 \nu_{e} \overline{\nu_{e}} \mathrm{H}, \mathrm{H} \rightarrow \mu^{+} \mu^{-}$events. For the righthanded beam polarisation state $\left(P_{e^{-}}, P_{e^{+}}\right)=(+0.8,-0.2)$ we expect less than 4 events.

## 2 Software

The event samples used in this analysis were created in the context of the ILD DBD mass production. The event generation is performed using WHIZARD [3] v1.95. The fragmentation is taken by PYTHIA [4]. The decays of $\tau$ leptons are handled by TAUOLA [5]. The simulation of the ILD detector is carry out with GEANT4 [6]. Since the events are generated as head-on collisions in WHIZARD, the crossing angle of 7 mrad is taken into account in the simulation step by boosting all particles accordingly. The event reconstruction is perform inside ILCSOFT [7] v01-16 framework. The analysis is done using ROOT [8] v5.32.00 and the TMVA [9] and RooFit [10] v3.50 software packages.

## 3 Event Samples

This section introduces the different samples used in the analysis. Table 1 lists the cross sections and the generated luminosity for all processes. Samples ea_ell, ae_ell, aa_4f and 5 f were generated with fast
simulation [11]. All the other samples were fully simulated. In Appendix A it is described the actual final state for every considered process.

| Processes | $\sigma[\mathrm{fb}]$ | $\mathrm{L}\left[\mathrm{ab}^{-1}\right]$ |  |  |

Table 1: Summary of event generation samples. The quoted cross sections and integrated luminosity are referred to the beam polarisation state: $\left(\mathrm{P}_{e^{-}}, \mathrm{P}_{e^{+}}\right)=(-0.8,+0.2)$, at $\operatorname{sqrt}(\mathrm{s})=1 \mathrm{TeV}$. The list of SM process with 4 fermions in the final state is exhaustive.

### 3.1 Signal Sample

The signal events used in this analysis have been created by generating events with a final state of $\nu_{e} \overline{\nu_{e}} H$ using WHIZARD. The decay of the higgs boson in PYTHIA was forced into two muons. The width of a $125 \mathrm{GeV} / \mathrm{c}^{2}$ Standard Model Higgs is negligible compared with the invariant mass resolution of the detector. The topology of the event comprises two muons and missing energy. Figure 2 shows the Feynman diagrams to $e^{+} e^{-} \rightarrow \nu_{e} \overline{\nu_{e}} \mathrm{H}, \mathrm{H} \rightarrow \mu^{+} \mu^{-}$in the ILC. In this analysis the contribution from Higgsstrahlung is negligible compared with WW-fusion.

### 3.2 Main Backgrounds

The main background comes for those processes with final state $\nu \bar{\nu} \mu^{+} \mu^{-}$, where the pair of muons are not from a Higgs decay. The initial state could be $e^{+} e^{-}$or $\gamma \gamma$. The ratio of the production cross

Figure 2: Feynman diagrams for signal: Higgsstrahlung (left) and WW-fusion (right). The WW-fusion is the dominant process at 1 TeV and $\left(P_{e^{-}}, P_{e^{+}}\right)=(-0.8,+0.2)$. In this analysis, the contribution from Higgsstrahlung process is negligible compared with WW-fusion.

sections between these backgrounds and signal exceed $10^{3}$. Table 1 list all the cross sections for those backgrounds.

## 4 Event Selection

The event selection is done in two steps. First, preselection of the events with two large energy muons in the final state, with invariant mass around to the Higgs mass peak. The final selection cuts are obtained by means an optimization process.

### 4.1 Preselection

Only events with two reconstructed muons with $E>15 \mathrm{GeV}$ are used. The identification of the muons is based on the deposited energy over the calorimeters. Objects not being produced in the primary vertex. are rejected with the requirement $\left|d_{0} / \Delta d_{0}\right|<5$.

The missing energy of the event $\#$ is defined as the center-of-mass energy less the total observed energy. A minimum value of $\#>300 \mathrm{GeV}$ is required to accept the event. The hadronic/semileptonic modes are rejected requiring less than 4 charged PFO's with energy higher than 15 GeV , and less than 3 leptons with $E>15 \mathrm{GeV}$. Table 2 shows the preselection cuts. No isolation requirement is made. The signal efficiency after these preselection requirements is $85 \%$.

| Muons |
| :---: |
| charged PFO |
| $E>15 \mathrm{GeV}$ |
| $E_{\text {calE }} /\left(E_{\text {calE }}+E_{\text {calH }}\right)<0.5$ |
| $\left(E_{\text {calE }}+E_{\text {calH }}\right) /\|\vec{P}\|<0.3$ |
| $\left\|d_{0} / \Delta d_{0}\right\|<5$ |
| Dimuon system |
| Opposite sign charges |
| $E_{\text {muon } 1}+E_{\text {muon } 2}<400 \mathrm{GeV}$ |
| $\left\|M\left(\mu^{+}, \mu^{-}\right)-125\right\|<30 \mathrm{GeV} / \mathrm{c}^{2}$ |
| $\quad \gg 300 \mathrm{GeV}$ |
| \# charged PFO's with $E>15 \mathrm{GeV}<4$ |
| \# charged leptons with $E>15 \mathrm{GeV}<3$ |

Table 2: Preselection cuts: $E_{\text {calE }}\left(E_{\text {calH }}\right)$ is the deposited energy on the electromagnetic (hadronic) calorimeter by the muon, $P$ is the momentum of the muon and $d_{0}$ its impact parameter. The cut on the maximum energy of the dimuon system select one of the process (WW-fusion) in Fig. 2.

### 4.2 Optimization

A cut based selection is performed using the following variables: $E_{T}, \notin, \mathrm{P}_{\mathrm{T}}\left(\mu^{+}\right)+\mathrm{P}_{\mathrm{T}}\left(\mu^{-}\right), \mathrm{P}_{\mathrm{T}}\left(\mu^{+}, \mu^{-}\right)$, $\cos \left(\mu^{+}, \mu^{-}\right)$. Optimization of the final cuts is performed using as score function the significance defined by:

$$
\begin{equation*}
\frac{S}{\sqrt{S+B}} \tag{1}
\end{equation*}
$$

where $S$ is the number of signal events passing selection on every scan with dimuon invariant mass inside $(124,126) \mathrm{GeV} / \mathrm{c}^{2} ; B$ is the number of background events inside sidebands (normalized to the signal window size). The sidebands are defined as: $(115,120)$ and $(130,135)$.

- Variables are scanned until we rise a stable point.
$-\operatorname{var}_{1} \rightarrow \operatorname{var}_{2} \rightarrow \operatorname{var}_{N-1} \rightarrow \operatorname{var}_{1}$
- If the $\operatorname{var}_{i}$ best value changes we scan $\operatorname{var}_{1}$ again.
- If no variables change in a full cycle $\left(\operatorname{var}_{1} \rightarrow \operatorname{var}_{1}\right)$ : we found a stable point.
- A new variable is added $\operatorname{var}_{N}$ and we scan it.
- New cycle of scans to find a new stable point: $\operatorname{var}_{1} \rightarrow \operatorname{var}_{2} \rightarrow \operatorname{var}_{N} \rightarrow \operatorname{var}_{1}$

The performed scans are included in Appendix C. After the last scan the significance (Eq. 1) reaches $\approx 2.3$.

Table 3 summarizes the optimization results. A requirement on the maximum energy deposited on the forward calorimeters is added to supress background contributions as $\gamma e^{ \pm} \rightarrow e l l \nu \nu, \gamma \gamma \rightarrow l l \nu \nu$. Figure 3 shows the dimuon invariant mass distribution before and after optimization.

Table 3: Result of the optimization.

$$
\begin{gathered}
\hline \hline E_{T}>40 \mathrm{GeV} \\
\not Z>550 \mathrm{GeV} \\
\mathrm{P}_{\mathrm{T}}\left(\mu^{+}\right)+\mathrm{P}_{\mathrm{T}}\left(\mu^{-}\right)>130 \mathrm{GeV} / \mathrm{c} \\
\cos \left(\mu^{+}, \mu^{-}\right)>-0.45 \\
\mathrm{BCal}<70 \mathrm{GeV} \\
\hline
\end{gathered}
$$

## 5 Branching Ratio Precision

In Section 4.2 it is shown that a statistical significance around $\sigma \approx 2.3$ is reached after the optimization process. This correspond with a statistical precision $\frac{\Delta(\sigma \cdot B r)}{\sigma \cdot B r}=\frac{1}{\sigma} \approx 43 \%$; similar value can be obtained from the data after applying the final selection: defining a signal mass window $(124,126) \mathrm{GeV} / \mathrm{c}^{2}$ the signal (background) contribution inside this window is $S=14.95(B=21.96)$, thereby we estimate the precision to be $\sqrt{S+B} / S \approx 41 \%$.

This value is sensitive to fluctuations in the number of events; signal sample was obtained from high statistics Monte Carlo samples, but the simulated statistics for the background is lower.

Figure 3: Dimuon Invariant Mass after preselection (left) and after optimization (right).

### 5.1 Pseudoexperiments

The background after optimization is flat (Fig. 3 with a value $\approx 4$. A number of $10^{5}$ independent background toy-samples were randomly generated using the background from data as template. For every sample, the value $B$ of events inside $(124,126) \mathrm{GeV} / \mathrm{c}^{2}$ is extracted and use to fill the distribution $\sqrt{S+B} / S^{1}$.

Figure 4 shows the distribution $\sqrt{S+B} / S$ over all these pseudoexperiments with $S(B)$ the number of signal (background) events within the mass window $(124,126) \mathrm{GeV} / \mathrm{c}^{2}$. A gaussian fit return the values: mean $=0.44, \sigma=0.015$.

Figure 4: Distribution $\sqrt{S+B} / S$ over all the pseudoexperiments; $S(B)$ are the signal (background) events passing selection with invariant dimuon mass inside $(124,126) \mathrm{GeV} / \mathrm{c}^{2}$.

## 6 Results

In Section 4.2 the statistical significance for $\sigma \cdot B r$ is estimated as $41-43 \%$. This value is obtained directly from the data samples after the final selection, and it is sensitive to fluctuations in the observed number of events.

[^0]In Sec. 5 an alternative toy Monte Carlo based approach is followed: many independent background samples are randomly generated from the background shape observed in the data. The number of signal events on the data, $S$, and the number of background events on every of the toy samples, $B$, both inside a mass window $(124,126) \mathrm{GeV} / \mathrm{c}^{2}$ are used to fill the distriution $\sqrt{S+B} / S(4)$. The expected statistical precision for $\sigma \cdot B r$ is estimated as $\pm 2 \sigma$ of the peak value of that distribution, thereby, $\frac{\Delta(\sigma \cdot B r)}{\sigma \cdot B r}=44 \pm 3 \%$.

## 7 Conclusion

The statistical uncertainty for a measurement of the cross section times branching ratio of a light Standard Model Higgs boson, with a mass of $125 \mathrm{GeV} / \mathrm{c}^{2}$ decaying into two muons has been evaluated. At the ILD, with a center-of-mass energy of 1 TeV , beam polarisation state $\left(P_{e^{-}}, P_{e^{+}}\right)=(-0.8,+0.2)$, and total integrated luminosity of $500 \mathrm{fb}^{-1}, \frac{\Delta(\sigma \cdot B r)}{\sigma \cdot B r} \sim 44 \pm 3 \%$.

## A Samples Description

This appendix list the final state of the samples used in this analysis.
In the final states of the 6 f _ttbar samples:

- e refers to an electron-positron and 1 other charged lepton.
- v refers to one neutrino.
- $x$ is up-type quark and $y$ is down-type quark (Some channels have one or more final quarks given explicitly).
- ae_ell, ea_ell, aa_4f and 5 f samples were generated with fast simulation.
- All other samples were fully simulated.

Full detail about all these samples can be found in [12].

## B Event Distributions

This appendix contains the event distributions after preselection.

## C Optimization Scans

This appendix contains the steps in the optimization process.

## D Event Distributions After Optimization

This appendix contains the event distributions after optimization.

## E Cut Flow Table

This appendix contains the analysis cut table. The quoted number of events referes to the Monte Carlo statistics (no applied weights); it includes all the beam polarisation states contribuing to the current process. The efficiency for every process can not be obtained just as the ratio of two columns. In order to obtain the efficiency it is necessary separate all the pure polarisation states taking in account their different cross sections. Thereby, the efficiency is defined as:

$$
\frac{N_{o b s}}{N_{e x p}}
$$

with $N_{o b s}\left(N_{\text {exp }}\right)$ the total number of observed (expected) events under the experimental conditions, that is, $L=500 \mathrm{fb}^{-1}$ and beam state polarisation $\left(P_{e^{-}}, P_{e^{+}}\right)=(-0.8,+0.2)$. The efficiency is included in the last column.
